Edition freeze 2026-07-16 Manuscript 2026-07-31

Abstract

Modern physics is accurate in fragments and fragmented in architecture. Sector models accumulate free parameters, and contested observables—especially the Hubble constant H_0 dual-anchor tension—expose the cost. We present a machine-checked, zero free-parameter scalar engine for Fluid Spacetime Omni-Theory (FSOT): a seed-derived vitality scalar $\text{raw_}S = \text{term}_1 + \text{term}_2 + \text{term}_3$ built only from π , e , φ , γ (Euler–Mascheroni), and Catalan’s G , with domain routes as preregistered folds rather than per-observable least-squares knobs.

Formally, the edition freeze reports `overall_ok: true` for **1,863** atomic obligations (Lean 4 primary authority; export to Coq/Rocq, Isabelle/HOL, F*, and Rust executable replay), bound to a SHA-256-pinned Python oracle. Empirically, contested-sector pooled median error is **0.030%** across 13 monitored observables (dual-anchor H_0 , σ_8 , BBN lithium proxy, hierarchy, w_a), versus a $\sim 15\%$ typical baseline tension scale for open Λ CDM/SM panels. Dual-anchor H_0 uses a bubble-bleed route (term_3 turbulence with `perceived_adjust` on term_1); preregistered PRED-001 places the FSOT bridge scalar strictly between Planck 2018 CMB and Riess et al. local anchors.

We scope this paper to the formal spine and contested cosmology—not a 400-domain monograph. The full 402-domain atlas (536,740 records; 394/394 domains under a $\leq 0.5\%$ green gate) is the living GitHub thesis. Readers can accept or reject claims by running the published verification bundle.

Keywords: formal methods; Lean 4; multi-prover verification; parameter-free models; Hubble tension; Fluid Spacetime Omni-Theory; reproducible science.

Software availability (required). Lean 4 formalization, five-prover obligation export, Python decimal oracle (`vendor/fsot_compute.py`), contested-sector ledger, preregistered predictions PRED-001–041, and one-command verification.

1 Introduction

1.1 The fragmentation problem

Twentieth-century physics delivered extraordinary local theories—general relativity, quantum mechanics, the Standard Model, and Λ CDM cosmology—each optimized inside institutional and mathematical boundaries. The empirical cost appears where boundaries meet: parameter proliferation, cross-sector tension (local H_0 versus CMB inference [6, 8, 9]), siloed success, and unified narratives without executable kill criteria.

Λ CDM explains CMB and large-scale structure with excellent *internal* consistency, yet the H_0 and σ_8 tensions remain open scientific problems [6, 8, 2, 7]. FSOT does not reject those *data*. It rejects the architecture: many knobs, many silos, no single engine that must survive formal and empirical gates at once.

1.2 Operational claim

Reality is modeled as a 25-dimensional fluid condensate. Observed regimes of space, time, matter, and measurement are folds of a single scalar field $\text{raw_}S$, computed from seed geometry with **no per-observable least-squares tuning**.

Routing coordinates (D_{eff} , $\delta\psi$, `recent_hits`, `observed`) are declared in domain manifests before comparison; failed green gates are ledger events, not silent parameter rescues.

1.3 Formal methods as scientific instruments

Proof assistants are standard in software verification; their use as *scientific instruments* is growing (formal chemical theory [1]; HepLean for high-energy physics [11]). Numeric scripts alone can drift. FSOT answers with: Lean 4 primary formalization; Coq/Rocq, Isabelle/HOL, F*, and Rust export; a hash-locked Python oracle; and preregistered predictions PRED-001–041.

1.4 Scope

Following the scope discipline of HepLean (selected HEP areas) [11] and Bobbin et al. (selected classical theories) [1], this paper is **focused**:

In scope	Out of main body (GitHub thesis)
Scalar engine; zero free parameters	Full 402-domain atlas narrative
Five-prover methodology	Fuels, wet-lab, linguistics stacks
Contested cosmology (H_0 , σ_8 , BBN)	Consciousness philosophy
Tight core physics domains	Propulsion volumes
Falsifiability + one-command repro	Optional ESP32 hardware

1.5 Contributions

1. **Unified scalar architecture.** $\text{raw_}S = \text{term}_1 + \text{term}_2 + \text{term}_3$ across 402 routed domains and 536,740 records without per-observable least squares.
2. **Cross-domain empirical context.** 394/394 public domains under a $\leq 0.5\%$ green gate; cross-domain pooled median 0.013%.
3. **Contested-sector readouts.** 0.030% pooled median on 13 observables vs $\sim 15\%$ typical open-panel baseline scale.
4. **Five-prover triangulation.** 1,863 atomic obligations (claims freeze) with `overall_ok: true`.
5. **Executable falsification registry.** PRED-001–041, kill criteria, one-command bundle [5].

1.6 Claim taxonomy

Category	Meaning	Examples
Proved	Machine-checked obligations	Sign theorems; <code>overall_ok</code>
Numerically verified	Oracle/hash match	Wave-1 caches
Empirical	External measured agreement	H_0 vs Planck
Interpretation	Narrative, not proved physics	Bubble-bleed ontology

Lean does **not** prove that FSOT is fundamental physics. It proves internal certificates at declared parameters. “Tension resolution” in the FSOT ledger means unified dual-anchor routing under preregistered discriminants—not community consensus on a new H_0 posterior.

2 The scalar engine

Formal authority: `FSOT/Formal/Scalar.lean` (Mathlib $\mathbb{R}$). Float mirror: `FSOT/Scalar.lean`. Decimal oracle: `vendor/fsot_compute.py` [5].

2.1 Seeds and intrinsic constants

Seeds: π , $e = \exp(1)$, $\varphi = (1 + \sqrt{5})/2$, Euler–Mascheroni γ , Catalan G . Intrinsic definitions (Lean), grouped for readability:

$$\alpha = \frac{\log \pi}{e \varphi^{13}}, \quad \psi_{\text{con}} = 1 - e^{-1}, \quad \eta_{\text{eff}} = \frac{1}{\pi - 1}, \quad (1)$$

$$\beta = \frac{1}{\exp(\pi^\pi + (e - 1))}, \quad \gamma_{\text{fold}} = -\frac{\log 2}{\varphi}, \quad \omega = \sin(\pi/e) \sqrt{2}, \quad (2)$$

$$\theta_s = \sin(\psi_{\text{con}} \eta_{\text{eff}}), \quad \text{poof} = \exp\left(-\frac{\log \pi/e}{\eta_{\text{eff}} \log \varphi}\right), \quad (3)$$

$$\text{acoustic_bleed} = \sin(\pi/e) \frac{\varphi}{\sqrt{2}}, \quad \sigma_\phi = -\cos(\theta_s + \pi), \quad (4)$$

$$\text{coherence} = (1 - \text{poof} \sin \theta_s) \left(1 + \frac{0.01 G}{\pi \varphi}\right), \quad (5)$$

$$\text{bleed_in} = \text{coherence} \left(1 - \frac{\sin \theta_s}{\varphi}\right), \quad (6)$$

$$\text{acoustic_inflow} = \text{acoustic_bleed} \left(1 + \frac{\cos \theta_s}{\varphi}\right), \quad (7)$$

$$\text{suction} = \text{poof} (-\cos(\theta_s - \pi)), \quad \text{chaos} = \frac{\gamma_{\text{fold}}}{\omega}, \quad (8)$$

$$p_{\text{new}} = \frac{\gamma}{e} \sqrt{2}, \quad c_f = \text{coherence} p_{\text{new}}, \quad (9)$$

$$k = \varphi \cdot \frac{\gamma}{e} \cdot \frac{\sqrt{2}}{\log \pi} \cdot \frac{99}{100}. \quad (10)$$

2.2 Parameter structure and terms

A domain evaluation uses $p = (N, P, D_{\text{eff}}, \text{recent_hits}, \delta\psi, \delta\theta, \rho, \text{scale}, \text{amplitude}, \text{trend_bias}, \text{observed})$.

$$\text{growth}(p) = \exp\left(\alpha \left(1 - \frac{\text{recent_hits}}{N}\right) \frac{\gamma}{\varphi}\right), \quad (11)$$

$$\begin{aligned} \text{term}_{1,\text{base}}(p) &= \frac{N P}{\sqrt{D_{\text{eff}}}} \cdot \cos\left(\frac{\psi_{\text{con}} + \delta\psi}{\eta_{\text{eff}}}\right) \\ &\cdot \exp\left(-\alpha \frac{\text{recent_hits}}{N} + \rho + \text{bleed_in} \delta\psi\right) \\ &\cdot (1 + \text{growth}(p) \text{ coherence}), \end{aligned} \quad (12)$$

$$\text{quirkMod}(p) = \begin{cases} \exp(c_f \sigma_\phi) \cos(\delta\psi + \sigma_\phi) & \text{if observed,} \\ 1 & \text{otherwise,} \end{cases} \quad (13)$$

$$\text{perceived_adjust}(D_{\text{eff}}) = 1 + p_{\text{new}} \log(D_{\text{eff}}/25), \quad (14)$$

$$\text{term}_1(p) = \text{term}_{1,\text{base}}(p) \cdot \text{perceived_adjust}(D_{\text{eff}}) \cdot \text{quirkMod}(p), \quad (15)$$

$$\text{term}_2(p) = \text{scale} \cdot \text{amplitude} + \text{trend_bias}, \quad (16)$$

$$\text{chaos_factor}(p) = 1 + \text{chaos} \frac{D_{\text{eff}} - 25}{25}, \quad (17)$$

$$\text{poof_suction}(p) = 1 + \text{poof} \cos(\theta_s + \pi) + \text{suction} \sin \theta_s, \quad (18)$$

$$\text{acoustic_factor}(p) = 1 + \text{acoustic_bleed} \frac{\sin^2 \delta\theta}{\varphi} + \text{acoustic_inflow} \frac{\cos^2 \delta\theta}{\varphi}, \quad (19)$$

$$\text{bleed_factor}(p) = 1 + \text{bleed_in} \sigma_\phi, \quad (20)$$

$$\text{term}_3(p) = \beta \cos(\delta\psi) \frac{N P}{\sqrt{D_{\text{eff}}}} \cdot \text{chaos_factor}(p) \cdot \text{poof_suction}(p) \cdot \text{acoustic_factor}(p) \cdot \text{bleed_factor}(p), \quad (21)$$

$$\text{raw_S}(p) = \text{term}_1(p) + \text{term}_2(p) + \text{term}_3(p), \quad (22)$$

$$\text{scaled_S}(p) = k \cdot \text{raw_S}(p). \quad (23)$$

Here `chaos_factor`, `poof_suction`, `acoustic_factor`, and `bleed_factor` are pure rewritings of the Lean product factors in `term3` (no new free parameters).

Zero free parameters (operational). Seeds and intrinsic constants are fixed mathematical definitions; domain routes are preregistered folds; verification performs no per-record least squares (`scripts/audit_parameter_count.py` $\rightarrow$ `ZERO_FREE`).

2.3 Wave-1 cosmological observables

From `FSOT/Formal/Cosmology.lean`, with cached cosmology scalar S_{cosm} :

$$H_0^{\text{FSOT}}(S_{\text{cosm}}) = 100 \left(1 + S_{\text{cosm}} \frac{\text{acoustic_bleed}}{\text{acoustic_inflow}}\right), \quad (24)$$

$$T_{\text{CMB}}^{\text{FSOT}}(S_{\text{cosm}}) = \varphi^2 + (\gamma/e) |S_{\text{cosm}}|, \quad (25)$$

$$n_s^{\text{FSOT}}(S_{\text{cosm}}) = 1 + S_{\text{cosm}} c_{\text{cosm}} \varphi^{1/\pi}, \quad c_{\text{cosm}} = 1/(\varphi \cdot 10), \quad (26)$$

$$\Omega_b h^2 \text{FSOT} = |S_{\text{cosm}}| (1 - S_{\text{quant}}), \quad (27)$$

$$\alpha_s(M_Z) = 1/(e\pi). \quad (28)$$

Interval certificates establish *internal* consistency at caches (e.g. $|H_0^{\text{FSOT}}(S_{\text{cached}}) - H_0^{\text{can}}| < 0.11$). External Planck/SH0ES agreement is empirical (Section 4).

3 Formal verification methodology

3.1 Three layers

(1) Formal object (Lean + multi-prover exports); (2) numeric oracle (hash-locked Python); (3) empirical ledger (measured vs seed-derived). Disagreement between Lean and Python fails the pipeline.

3.2 Oracle gate

Authority: `vendor/fsot_compute.py`. Edition SHA-256:

D1D38A185487B452E470AC68ECE2EB45AEB1CA9CE25FC9BF9564C19633FFBE70

3.3 Lean 4 primary formalization

Toolchain: Lean 4.31.0 + Mathlib v4.31.0 [4, 10]. Modules: `Scalar`, `Domains`, `Cosmology`, extension `*Priors`.

Representative theorems (`FSOT/Formal/Domains.lean`, `Cosmology.lean`):

Theorem	Informal statement
<code>cosmological_raw_S_negative</code>	$\text{raw_}S(p_{\text{cosm}}) < 0$
<code>dark_energy_raw_S_negative</code>	$\text{raw_}S(p_{\text{DE}}) < 0$
<code>cmb_raw_S_negative</code>	$\text{raw_}S(p_{\text{cmb}}) < 0$
<code>medical_raw_S_positive</code>	$\text{raw_}S(p_{\text{med}}) > 0$
<code>quantum_raw_S_positive</code>	$\text{raw_}S(p_{\text{q}}) > 0$
<code>h0_fsot_cached_approx_value</code>	$ H_0^{\text{FSOT}} - H_0^{\text{can}} < 0.11$

3.4 Five-prover triangulation

Framework	Role	Status
Lean 4	Primary formal authority	PASS
Coq/Rocq	Independent export replay	PASS
Isabelle/HOL	Independent export replay	PASS
F*	Boot scalar kernel	PASS
Rust	Executable obligation replay	PASS

Authoritative artifact: `data/cross_proof_verification_report.json` $\rightarrow$ `overall_ok: true`; claims freeze atomic obligations **1,863** (`data/publication_claims_manifest.json`; public tag `v2.6-arxiv-paper01` matches this count). Scientist acceptance: `overall_ok` and atomic count ≥ 1863 .

3.5 Empirical error metric

For pairs (m_i, c_i) (measured, computed):

$$\varepsilon_i = 100 \cdot \frac{|c_i - m_i|}{\max(|m_i|, \epsilon_{\text{floor}})}, \quad \tilde{\varepsilon} = \text{median}(\varepsilon_1, \dots, \varepsilon_n). \quad (29)$$

GREEN gate: $\tilde{\varepsilon} \leq 0.5\%$. Cross-domain headline: median of per-domain $\tilde{\varepsilon}$ (not a global re-fit).

3.6 What formalization does not prove

Not physical necessity; not universal quantification over all parameter sweeps; not community adoption of a new cosmological posterior. F* scope is the boot kernel shell; full spine is Lean+Coq+Isabelle+Rust+Python.

4 Contested-sector results

4.1 Headline

Metric	FSOT (freeze)	Typical baseline
Pooled median error	0.030%	~15%
Observables monitored	13	—

Raw freeze value: 0.029749% in `data/publication/CONTESTED_SECTOR_WATCH.md` and `publication_claims_manifest.json`.

4.2 Selected observables

Observable	FSOT err. %	Reference
H_0 SH0ES vs Planck tension	0.027	[8, 6]
H_0 Carnegie vs Planck	0.227	[3]
S_8 Planck vs DES Y3	0.195	[2]
Lithium problem factor	0.316	BBN gap
σ_8	0.003	open panel
w_a	0.0006	DESI-era panel
H_0 Planck CMB route	0.193	[6]
H_0 SH0ES local route	0.662	[8]

The headline **0.030%** is a *pooled median* over the contested panel, so it is dominated by the tightest rows (e.g. w_a , σ_8 , N_{eff} -class open panels). Higher single-row values such as lithium (0.316%) and the SH0ES local H_0 route (0.662%) remain far below the repository’s ~15% typical open-panel baseline scale and still sit under the 0.5% green gate; they do not contradict the median headline.

4.3 Bubble-bleed and PRED-001

Interpretation tier with formal hooks. In the scalar engine, small-scale fluid structure lives in term_3 (Eq. (21)): acoustic bleed/inflow, poof/suction, and chaos folds derived from the seeds—not fitted per anchor. Large-scale / observer routing enters through perceived_adjust on term_1 (Eqs. (14)–(15)) and, for Wave-1 readouts, through $H_0^{\text{FSOT}}(S_{\text{cosm}})$ (Eq. (24)). Lean packages these couplings under the `bubble_bleed_*` obligation family. Dual anchors are not separately least-squares fitted: CMB-route and local-route evaluations share seeds and differ by preregistered route parameters.

Quantity	Value
Planck 2018 H_0	$67.36 \pm 0.54 \text{ km s}^{-1} \text{ Mpc}^{-1}$
FSOT worked CMB route	$67.270 \text{ km s}^{-1} \text{ Mpc}^{-1}$
Relative error	0.13%
PRED-001 bridge scalar	$70.75 \text{ km s}^{-1} \text{ Mpc}^{-1}$
SH0ES local anchor	$73.04 \text{ km s}^{-1} \text{ Mpc}^{-1}$
PRED-001 discriminant	strictly between Planck and SH0ES

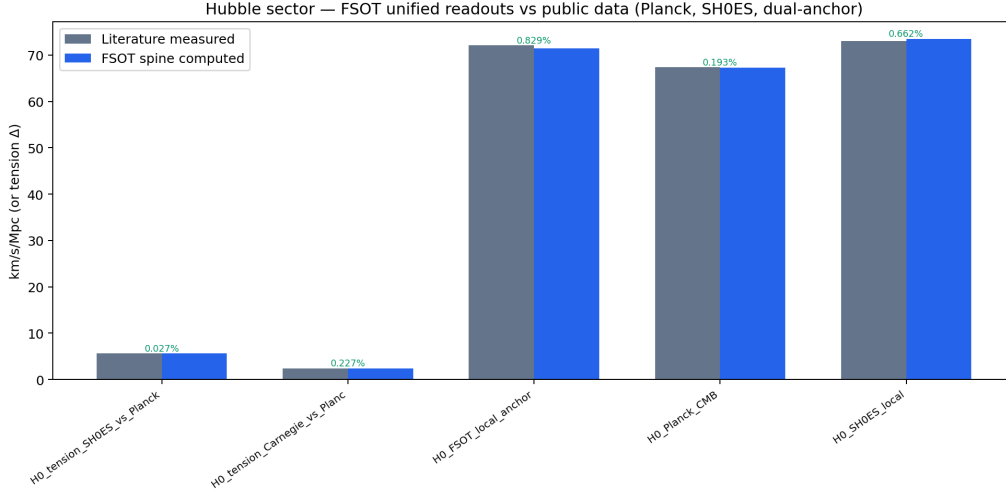

Figure 1: H_0 landscape: dual-anchor routes and FSOT bridge. Artifact: `data/figures/h0_landscape.png`. One-line regenerate (from a clone of [5]): `python scripts/build_scientific_figures.py` (also produced by `python scripts/run_publication_verification_bundle.py`).

Preregistered cosmology locks (declared before panel refresh in `data/preregistered_predictions_manifest`)

ID	Name	Discriminant
PRED-001	H_0 bridge scalar	strictly between Planck and SH0ES
PRED-002	S_8 effective lensing	between Planck and DES
PRED-005	lithium problem factor	within 10% of observed gap

Caution. The observational community often quotes H_0 tension in σ under Λ CDM [8, 7]. This paper’s primary metrics are relative percent error and preregistered discriminants—not a replacement σ claim or a full CMB likelihood re-analysis.

5 Selected core-domain empirical closure

Domain	Records	Median err. %	Tier
Cosmology	347	0.0007	A_strong
Astrophysics	305	0.0006	A_strong
High-energy physics	151	0.0036	A_strong
Atomic physics	116	0.0010	A_strong

Context: 402 domains; 536,740 records; 394/394 green under $\leq 0.5\%$; cross-domain pooled median 0.013%. Full atlas: `data/publication/domain_atlas.csv` [5].

6 Falsifiability and independent reproduction

6.1 One-command bundle (Tier 1)

```
git clone https://github.com/dappalumbo91/FSOT-2.1-Lean.git
cd FSOT-2.1-Lean
pip install -r requirements.txt
python scripts/run_publication_verification_bundle.py
```

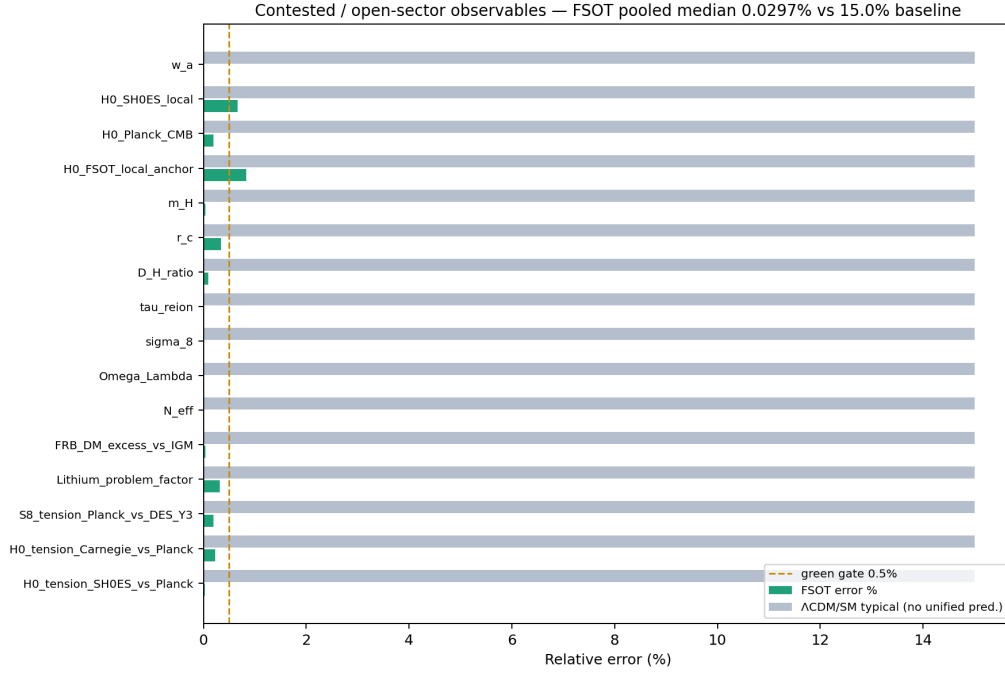

Figure 2: Contested-sector FSOT errors versus typical open-panel baseline scale. Artifact: `data/figures/contested_fsot_vs_lcdmd.png`. Regenerate with `python scripts/build_scientific_figures.py` or the publication verification bundle.

Does **not** re-ingest live APIs; uses on-disk portable benchmarks (public clone ≈ 0.5 GB working tree). `requirements.txt` includes `matplotlib>=3.8` (commit `8a44947`) so figure regeneration works on a bare install. Author clean-clone reproduction: exit code 0 in ~ 25 s (report: paper package `CLEAN_CLONE_REPRO_REPORT.md`).

6.2 Expected artifacts

- `data/publication_claims_manifest.json`
- `data/contested_observables_closure.json`
- `data/benchmark_margin_audit.json`
- `data/figures/contested_fsot_vs_lcdmd.png`, `h0_landscape.png`, `spine_walkthrough.png`

6.3 Automated freeze checker

The paper package ships `verify_paper_claims.py`:

```
export FSOT_ROOT=/path/to/FSOT-2.1-Lean
python verify_paper_claims.py --strict-hash
```

Exit code 0 indicates freeze checks passed on available artifacts.

6.4 Lean (Tier 2) and five-prover (Tier 3)

```
lake exe cache get && lake build
python scripts/fsot_verification_runner.py --portable
python scripts/run_publication_verification_bundle.py --full-cross-proof
```

Expect: `certificate.json` with `sorry_count_formal=0`; `cross_proof_verification_report.json` with `overall_ok: true`.

FSOT five-prover obligation map

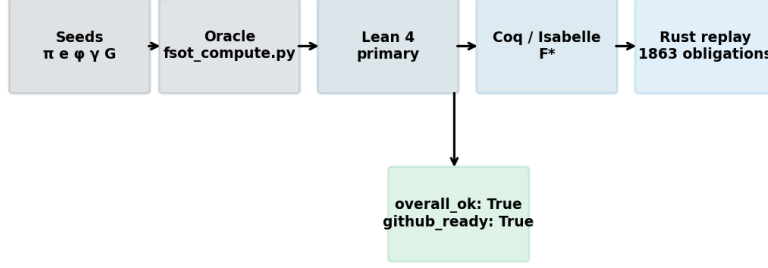

Figure 3: Five-prover obligation triangulation map. Artifact: `data/figures/obligation_map_five_provers.png`. Regenerate with `python scripts/build_obligation_map_figure.py` (or the publication figure pack scripts in [5]).

6.5 How to reject this paper

1. Clean checkout of freeze commit fails the publication bundle.
2. Contested pooled median far from 0.030% after regeneration.
3. Parameter audit no longer reports zero free per-row fits.
4. `sorry_count_formal` > 0 or Lean build fails on freeze toolchain.
5. `overall_ok: false` with documented toolchains installed.
6. Oracle hash differs from freeze without documented authority repin.

Narrative disagreement without running the ledger is outside the falsification contract. ESP32 absence does not falsify main claims.

7 Discussion

7.1 What this paper contributes relative to adjacent work

Lean-based formalizations of scientific theories emphasize making premises and derivations explicit (e.g. adsorption isotherms and thermodynamic structure [1]; digitalization of high-energy physics definitions [11]). FSOT sits in that tradition for the *scalar engine*, then adds two layers those works do not attempt: (i) multi-prover *export and replay* of a large obligation surface bound to a hash-locked numeric oracle; (ii) a contested *empirical* ledger with preregistered discriminants on H_0 , S_8 , and related open panels [6, 8, 3, 2, 7].

Early-dark-energy and other Λ CDM extensions typically introduce new dynamical fields or parameters to move H_0 [7]. FSOT’s architecture is different: fixed seeds, preregistered routes, and an executable kill ledger—not a one-parameter patch of the Planck likelihood.

7.2 Strengths and limitations

Strengths. Parameter-free seed arithmetic; machine-checked sign/interval certificates at canonical parameters; five-prover triangulation; preregistered contested discriminants; public one-command reproduction [5].

Limitations. (1) Certificates are not physical necessity. (2) A single decimal oracle is a specification risk mitigated—not eliminated—by multi-prover export. (3) The $\sim 15\%$ “typical baseline” is a sector-scale repository characterization of open-panel tension, not a substitute for survey-specific covariance matrices. (4) The 402-domain atlas is not defended domain-by-domain in this paper. (5) Bubble-bleed is an interpretive mechanism with formal hooks; it is not a proof that fluid ontology is fundamental. (6) Full σ -level Bayesian re-analysis of Planck+SH0ES is future work.

7.3 Reading the claim stack

When citing this work, separate layers: *proved* (Lean/export obligations), *numerically verified* (oracle hash gate), *empirical* (percent errors vs external anchors), *interpretation* (fluid narrative). Collapsing those layers is the main way the argument is misread.

8 Conclusion

We presented a focused claim: a machine-checked, zero free-parameter scalar engine—Lean 4 primary, five-prover triangulated—supplies unified, preregistered contested cosmological readouts, including dual-anchor H_0 via bubble-bleed routing, at 0.030% pooled median error across 13 observables, with 1,863 atomic obligations closed under `overall_ok: true` in the edition freeze. The 402-domain atlas remains the living GitHub thesis <https://github.com/dappalumbo91/FSOT-2.1-Lean>. Clone the freeze commit, run the bundle, accept or reject on executable terms.

Acknowledgments

Grok and Cursor assisted manuscript assembly. Generative AI tools are not co-authors; the author retains full scientific responsibility (arXiv AI-language-tool policy). Numerical claims are intended to reproduce from the public repository.

Data and code availability

Primary repository: <https://github.com/dappalumbo91/FSOT-2.1-Lean>

Recommended pin: tag `v2.6-arxiv-paper01` (commit `8a44947`).

One-command: `python scripts/run_publication_verification_bundle.py`.

Independent claim checker and freeze pins ship with the paper package (`FREEZE.yaml`, `SCIENTIST_REPRODUCE.md`, `verify_paper_claims.py`).
